

The Prototype phases

★ Requirements gathering and analysis

During this phase, the system's desires are defined precisely . System users are also interviewed to determine what they expect from the system.

★ Quick design

This phase mainly consists of a preliminary or quick design. The system's basic designs are formed at this point but its not a complete design.

This provides users with quick overview of the system

★ Build a prototype

This is a small low-level working model of the desired system. An actual prototype is intended to support the knowledge gained from quick design.

★ Initial user evaluation

The proposed system is presented to the client for testing to investigate a model's performance strengths and weaknesses.

Customer feedback and suggestions are gathered and forwarded to the developer.

★ Refining prototype

If the user is dissatisfied by the current model, improvements are made to respond to clients feedback and suggestions.

Until the user is satisfied with the upgraded model, a final system is then made based on user feedback.

★ Implementing the product

After the final system was fully tested and sent to production, and all the improvements made, it was then released to the client.

★ Maintenance

The program is then run on a regular basis to reduce downtime and prevent major failures .
